

# MATH 308 Assignment 12: Sequences in Coin Flips

Nakul Joshi

March 26, 2014

## 1 Expected Number of Occurrences      2 Probability of Occurrence

For each coin flip  $i$ , let  $X_i$  be the event that the sequence 01111111 occurs starting at position  $i$ . Then:

$$\mathbb{E}(\mathbb{1}(X_i)) = \begin{cases} 2^{-8}, & \text{if } 1 \leq i \leq 93 \\ 0, & \text{if } i > 93 \end{cases}$$

So, the expected number of occurrences is:

$$\begin{aligned} N &= \mathbb{E} \left( \sum_{i=1}^{100} \mathbb{1}(X_i) \right) \\ &= \sum_{i=1}^{100} \mathbb{E}(\mathbb{1}(X_i)) \\ &= \sum_{i=1}^{93} \mathbb{E}(\mathbb{1}(X_i)) \\ &= 93/2^8 \approx 0.363 \end{aligned}$$

Using the result above, we can approximate the coin-flipping experiment as a Poisson process with rate parameter  $\lambda = 93/2^8$ .

The requisite probability can then be calculated as `1-ppois(0,93/2^8)`, which comes out to  $\approx 0.30$ , which is slightly under the result from Assignment 2.

# MATH 308 Assignment 15: Exercises 5.10

**5**

**a)**

Suppose that cookie orders are represented such that, for example, an order of 1 sugar, 2 chocolate chips, 0 oatmeal, 0 peanut butter, and 2 ginger snaps is given by  $|c|cc|cc|$ . Then, two of the bars are fixed, giving the string  $|??????|$ , where the nine ? symbols are to be replaced by five  $c$ 's and two  $|$ 's. If we choose 5 distinct positions in which to place the  $c$ 's, the positions of the remaining  $|$ 's is fixed. Thus, the number of possible cookie orders is  $\binom{9}{5}$ .

**b)**

More generally, we can use 'cookie types' to represent occurrences of particular elements in the chosen sets. Then, fixing the position of two  $|$ 's leaves  $n + 1 - 2 = n - 1$   $|$ 's and  $n$   $c$ 's, for a total of  $2n - 1$  symbols. Picking element members requires  $n$  position choices, giving the total number of set choices as  $\binom{2n-1}{n}$ .

**c)**

For a sample  $S$  of size  $n$ , each bootstrap sample represents the choice of  $n$  elements from  $S$  with replacement. Thus, the number of bootstrap samples is as above  $\binom{2n-1}{n}$ .

**6**

**a)**

The number of bootstrap samples with  $k_1$   $a_1$ 's,  $k_2$   $a_2$ 's  $\dots k_n$   $a_n$ 's is the same as the number of permutations of the string

$$\underbrace{\overbrace{a_1 a_1 \dots a_1}^{k_1 \text{ times}} \overbrace{a_2 a_2 \dots a_2}^{k_2 \text{ times}} \dots \overbrace{a_n a_n \dots a_n}^{k_n \text{ times}}}_{n \text{ symbols}}$$

Using the formula for string permutations with repeated characters, this yields

$$\frac{n!}{k_1! k_2! \dots k_n!}$$

which, by definition, equals

$$\binom{n}{k_1, k_2 \dots k_n} \quad \square$$

**b)**

A bootstrap sample with  $k_i$   $a_i$ 's requires choosing  $k_i$  of  $n$  positions, after which the remaining  $n - k_i$  positions can be filled by any of the remaining  $n - 1$  elements. Thus, the number of such samples is:

$$(n - 1)^{n - k_i} \binom{n}{k_i}$$

The total number of bootstrap samples is simply  $n^n$ . Thus, the required probability is

$$\frac{(n - 1)^{n - k_i}}{n^n} \binom{n}{k_i}$$

The evenness of  $N$  does not seem to affect the histograms, but increasing  $N$  reduces the spread.
